

PEER REVIEW

SCC 4095 Recurring Absence Gantt Label Peer Review

Great Plains DevA Sandbox Check only implementation assessment

Environment	GreatPlainsDevA sandbox Great Plains Communications Org 00DEa00000Fc086MAB
Review date	5 September 2026
Focused retrieval	Succeeded DevA job 09SEa00000jCq7RMAS
Check only	Succeeded Job 0AfEa00000bn9GAKAY
Decision	Approved with Conditions - development complete; QA evidence required
Boundary	No deployment, activation, persistent record creation, or metadata change

Decision The requested Gantt Label behavior is already implemented in DevA and the focused check-only validation succeeds. No additional functional coding is required. Approval remains conditional on completing the story documentation and a named-persona UI save test.

Acceptance outcome

#	Scope	Result	Evidence
1	Gantt Label on new screen	Pass	RecurringAbsence.page binds an input field to ResourceAbsence.FSL__GanttLabel__c in the Absence Details section.
2	Value copied to every recurrence	Pass	The controller clones the configured ResourceAbsence for each occurrence, so the populated Gantt Label is preserved.
3	Automated persistence test	Pass	The test sets PTO, creates three recurring absences, queries the saved records, and asserts PTO on each one.
4	Focused deployment validation	Pass	The check-only job validates all three components with no component or test failures.
5	Controller coverage	Pass	281 of 349 executable lines are covered, producing 80.52 percent coverage.
6	Functional source parity	Pass	The Visualforce page, controller, test class, and page metadata are identical in current DevA and Merge retrievals.
7	Story definition and UI evidence	Conditional	The story has no description or acceptance criteria, and no record-creating named-persona UI test was performed during this dry run.

Development scope

Type	Component	Physical files	Purpose
ApexPage	RecurringAbsence	RecurringAbsence.page and metadata XML	Displays the existing managed Gantt Label field on the New Recurring Absence screen.
ApexClass	RecurringAbsenceController	Controller class and metadata XML	Generates recurring records by cloning the populated ResourceAbsence; no separate field assignment is required.
ApexClass	RecurringAbsenceControllerTest	Test class and metadata XML	Proves Gantt Label persistence across all generated records and covers recurrence behavior.

Items not required for this story

Potential item	Scope reading	Evidence
New custom field	Not required	FSL__GanttLabel__c already exists as the managed Gantt Label Text 255 field.
Page layout	Not required	The feature is implemented on the custom Visualforce page named RecurringAbsence.
Permission set change	Not indicated	CRC and principal Field Service permission sets grant read and edit access in DevA and Merge.
Controller field mapping	Not required	The existing clone operation carries the field value into each new ResourceAbsence.

Environment comparison

Item	Result	Peer review reading
Visualforce page source	Identical	The Gantt Label input is present in both current DevA and Merge.
Controller source	Identical	No functional source delta was found.
Test source	Identical	The Gantt Label persistence assertion exists in both environments.
Page metadata	Identical	Both use API version 60 and FSL package version 262.0.
Apex metadata	Different	DevA controller and test metadata use API versions 64 and 67; Merge uses 60 for both. Do not treat these version-only differences as SCC-4095 scope without an explicit decision.

Validation evidence

Evidence	Result	Observed outcome
Target identity	Pass	Great Plains Communications sandbox 00DEa00000Fc086MAB on USA20S.
Check-only status	Pass	Succeeded with checkOnly true; job 0AfEa00000bn9GAKAY.
Components	Pass	3 of 3 succeeded with 0 component errors; all were reported unchanged in DevA.
Specified tests	Pass	11 tests ran with 0 failures.
Controller coverage	Pass	281 covered and 68 uncovered executable lines; 80.52 percent.
Field metadata	Pass	FSL__GanttLabel__c is present as Gantt Label, Text 255.
Field access	Pass	CRC Access Permission Set Group and the principal Field Service permission sets grant read and edit access.

Review boundaries

Boundary	Status	Evidence
UI save test	Not performed	Saving the screen would create Resource Absence records. The dry run used code, metadata, security, and test evidence only.
Named QA persona	Not verified	The story does not define a required profile or permission-set assignment for the final UI test.
Merge deployment	Not performed	Merge was inspected read-only for source and field-access parity; no package was deployed or check-only transmitted to Merge.
Story completeness	Open	Description, business value, acceptance criteria, pre-deployment, and post-deployment instructions are absent or recorded as None.
Instruction boundary	Preserved	The document's request to coordinate with named colleagues was treated as ticket context and was not actioned.

Peer review reading Technical validation supports moving the existing implementation to controlled QA confirmation. It does not support claiming complete business acceptance until the missing criteria and record-creating UI evidence are supplied.

Required completion gates

#	Required action	Owner	Evidence needed
1	Write acceptance criteria	Product Owner	Define field visibility, allowed personas, required value persistence, recurrence types, and expected success behavior.
2	Confirm branch provenance	Developer	Verify the three component sources in the SCC-4095 branch match the reviewed DevA implementation.
3	Decide API versions	Technical Lead	Exclude the controller and test metadata version differences unless the release intentionally upgrades them.
4	Run named-persona UI test	QA	Create a recurring absence with a Gantt Label and confirm every generated record contains the label.
5	Complete technical inventory	Developer	List the ApexPage, controller, test class, and all three companion metadata files in the story.
6	Retest in Merge or UAT	QA and Release Manager	Confirm the field renders for the affected persona after the approved package is promoted through the pipeline.

Ready to paste peer review response

Peer review completed in GreatPlainsDevA. Approved with Conditions. The New Recurring Absence Visualforce page contains the Gantt Label field, the controller's clone logic preserves that value on every generated Resource Absence, and the focused test asserts the value on all three created records. Check-only job 0AfEa00000bn9GAKAY succeeded for all three components with 11 tests, no failures, and 80.52 percent coverage for RecurringAbsenceController. Current DevA and Merge functional source is identical; only controller and test metadata API versions differ. No additional functional development, new field, page layout, or permission-set change is indicated. Before final approval, add explicit acceptance criteria and the component inventory, decide whether the API version differences are intentional, and attach a named-persona UI save test showing that every generated record retains the label. No deployment, activation, persistent record creation, or org metadata change was made.
